

Top box = Ontology (Schema / Design)

```
Entity Types:
Document
Referenced_Document

Relationship Types:
Document --references--> Referenced_Document
Document --describes--> Referenced_Document
Document --uses--> Referenced_Document
Document --managed_by--> Referenced_Document
Document --supports--> Referenced_Document
Document --contains--> Referenced_Document
Document --implements--> Referenced_Document
...
```

These are the **classes and relationship types** defined by your ontology.

- **Document** is a class (every XML document belongs to this class).
- **Referenced_Document** is a class (documents that are referenced through hyperlinks).
- **references, uses, describes, etc.** are relationship types (predicates) extracted by the LLM.

Bottom box = Entities and Relationships (Actual Data)

```
MMCT --references--> TEDS

TEDS --describes--> Fuel_System

MMCT --uses--> WDM

Fuel_System --managed_by--> TEDS

SRM --supports--> MMCT
```

These are the **actual RDF triples** stored in your knowledge graph.

If you want to show the ontology more formally

```
Top box = Ontology (Schema)

Classes:
  • Document
  • Referenced_Document

Object Properties:
  • references
  • uses
  • describes
  • managed_by
  • supports
  • contains
  • implements

Datatype Properties:
  • label
  • sourceReference
  • targetReference
  • documentContent
  • relationship_description
  • relationship_strength
  • link_type
```

One suggestion

Looking at your notebook, I would simplify the ontology even further.

Instead of having:

```
Document
Referenced_Document
```

I would use:

```
Top box = Ontology (Schema)

Entity Type:
  Document

Relationship Types:
  Document --references--> Document
```
